Abstract

The feature of superficially porous (core shell) particle used as a highly efficient material is existence of a core, a thin porous layer and narrow particle size distribution, which lead to higher efficiency than totally porous particle. Recently a core shell particle with wide pore for biomacromolecular separations has developed by a few manufacturers. It has been said that thin porous layer of core shell particle have an advantage for separation of large molecules such proteins because a diffusion coefficient becomes small to proportional to a molecular weight and a mass transfer speed also decreases. In this paper, thickness of porous layer of core shell particle may and the proteins.

2 kinds of thickness of porous layer such as 0.2 µm and 0.5 µm thickness were applied for separation of standard protein samples. One was 3.4 µm particle size, 0.2 µm porous layer and 15 m2/g specific surface area and another was 2.6 µm, 0.5 µm and 15 m2/g. Separation was achieved using a gradient elution with 0.1% trifluoroacetic acid and acetonitrile including 0.08% trifluoroacetic acid. On fast separation, 0.2 µm of porous layer showed sharper peaks than 0.5 µm of porous layer. However at 80 degree Celsius and using 60 min gradient time program, 0.5 µm of porous layer showed much sharper peaks than 0.2 µm of porous layer. It was considered that 0.5 µm of porous layer had the a wider specific surface area than 0.2 µm of porous layer and this wider specific surface area leaded separation efficiency concerning the partition interaction on the stationary phase to be large. Better separation of proteins contributes not only the thin porous layer but also the large surface area.
